REVISTA AIDIS

de Ingeniería y Ciencias Ambientales:
Investigación, desarrollo y práctica.

Temática y alcance

La Revista AIDIS de Ingeniería y Ciencias Ambientales: Investigación, desarrollo y práctica es una publicación electrónica cuatrimestral coeditada por AIDIS y el Instituto de Ingeniería UNAM. Publica contribuciones originales de calidad y actualidad evaluadas por pares, dentro de su área de competencia. Se presentan trabajos que abarcan aspectos relacionados con el conocimiento científico y práctico, tanto tecnológico como de gestión, dentro del área de Ingeniería y Ciencias Ambientales en Latinoamérica.

El enfoque es multidisciplinario, buscando contribuir en forma directa a la generación de conocimiento, al desarrollo de tecnologías y a un mejor desempeño profesional. Entre los temas cubiertos por la revista están los siguientes: agua potable, calidad de agua, aguas residuales, residuos sólidos, energía, contaminación, reciclaje, cambio climático, salud ambiental, nuevas tecnologías, ética, educación, legislación y política ambiental, gestión ambiental, sostenibilidad y participación social, entre otros.

Cada edición muestra los trabajos que derivan del arbitraje académico estricto de carácter internacional. También se publican números especiales de temas particulares que fueron presentados en los diversos Congresos Interamericanos realizados por la Asociación Interamericana de Ingeniería Sanitaria y Ambiental (AIDIS) y que en forma adicional fueron sometidos al proceso de revisión interno de la revista.

Abstract

In order to assess the effect of vitamin C supplementation at different feeding rates on the zootechnical, environmental and microbiological performance of the Nile tilapia, *Oreochromis niloticus*, grown in domestic wastewater treated in stabilization ponds, we used nine 50 m³ tanks divided into three experimental treatments with four replicates, varying the amount of feed and supplementing the dosage of Vitamin C up to 1500 mg per kg of feed. Based on the analysis of the assessed parameters, we found that the treatment with the best results was the one with a quarter of feed supplemented with 1500 mg of vitamin C, because when evaluating the zootechnical performance this was statistically even with the other treatments, already in relation to the environmental indicators it was observed that the fish culture acts as a polishing to the treatment of the effluent, in relation to the microbiological indicators it was observed that the produced fish was within the sanitary conditions recommended by the current legislation.

Keywords: ascorbic acid, stabilization ponds; *Oreochromis niloticus*, reuse in pisciculture.

ECPONTOS: ESTUDO DE CASO DOS EQUIPAMENTOS URBANOS PARA A GESTÃO DE RESÍDUOS SÓLIDOS

ECPONTOS: CASE STUDY OF URBAN EQUIPMENT FOR THE MANAGEMENT OF SOLID WASTE

Recibido el 20 de mayo de 2018; Aceptado el 6 de febrero 2019

Abstract

The use of equipment known as Point of Support (PA) or Ecopontos in the integrated management of urban solid waste (RSU) has occurred in several cities in the world and some in Brazil. In this sense, this article has as main objective to make an evaluation of the existing system of Ecopontos in the city of São José do Rio Preto, SP. To do so, data were collected on such equipment, such as quantities and types of waste received and also an evaluation of the system by users divided into three segments: residents (residents), small cargo transporters and ecoponto operators. As a result, it was observed that the use of AP was efficient for receiving small volumes delivered voluntarily. However, the data indicated problems in the system, showing the need for a more efficient management. It can be considered that PAs are an equipment that improves MSW management, in the case studied, absorbing several typologies of MSW, such as 23% of construction waste and with approval by the majority of users in the evaluated segments.

Keywords: MSW, support point, Ecoponto, waste management.

ANALYSIS OF HYDROLOGIC TIME SERIES IN A SMALL RURAL AMAZONIAN CATCHMENT

Recibido el 30 de mayo de 2018; Aceptado el 29 de marzo 2019

Abstract

This study verifies the hydrological relationships of homogeneity and tendency of rain, flow and water level, and the climatic variability of these precipitations in a Prata river basin, located in the municipality of Capitão Poço-PA. For precipitations, data from a historical series of 30 years were used. For flow rates and water levels data were used in the period from 1988 to 2005. The behavior of total precipitations, flows and average dimensions was analyzed by the method of the Pettitt homogeneity test and trend and magnitude test provided by Mann-Kendall and Sen's Tests and the correlation between the variables in the period of their simultaneous occurrences. The climatic phenomena El Niño and La Niña influence directly causing anomalies on the rainfall. In the Prata catchment, the flows and coasts simultaneously have the same behavior as a function of time, however, these variables have a weak correlation with precipitation. In general, no significant trends were observed in the behavior of rainfall and flow series. The average levels, in general, are not homogeneous and have positive trends that may be related to the dynamics of land use and land cover. The analysis of trends for rainfall in the basin of the Prata River is compatible with macro analyzes focused on the region.

Keywords: Pettitt, Mann-Kendall, Sen's, climatic phenomena.

ANALYSIS OF THE VIABILITY OF MINI COMPOSERS AS AN ALTERNATIVE METHOD OF DISPOSAL OF LEAVES IN PLACES OF SMALL GENERATION OF ORGANIC WASTES

Recibido el 31 de mayo de 2018; Aceptado el 28 de marzo 2019

Abstract

Considering the increase in urban solid waste, alternatives became necessary to decrease the destination of recyclable and organic wastes to landfills. It is highlighted, then, the composting process as allied to the disposal of organic solid waste. The present study aims to evaluate the viability of mini composters as an alternative to the discard of leaves in locals of low generation. Four reactors were produced: two of Polyethylene terephthalate (PET), of volume equal to 2 liters and two 5-liter containers. The monitored parameters along the 142 days were moisture (weekly), temperature (twice a week through a thermometer of internal measurement), and height (also twice a week). Shapiro-Wilk test, Kruskal-Wallis with post-hoc by Nemenyi and Pearson's correlation test and by Multiple Comparisons were applied, using software R. It was observed that the maximum and minimum temperature amplitudes for the reactors were 32.5°C (SC5L) and 21°C (CC5L), respectively, maintaining below 30°C from most of the experiment. Only CC5L presented a statistical difference ($p<0.05$) to the ambient temperature. It was also verified that the reactor CC2L showed the biggest reduction in volume (61.4%) and intense brownish color, evidencing an advanced stage of material degradation. Hence, it was concluded that this composting process could be used as an adequate alternative for the discard of leaves in a location of low wastes generation, being a procedure of easy execution and maintenance.

Keywords: green waste, composting, waste management.

TEMPORARY ANALYSIS OF WATER QUALITY AT URBAN RIVERS

Recibido el 14 de junio de 2018; Aceptado el 11 de junio 2019

Abstract

Anthropogenic activities generate degradation of the water quality of water bodies, making it extremely important to analyze chemical, physical and biological parameters for water resources planning and management. The objective of this study was to evaluate the changes in water quality of water bodies located in the city of Campo Grande-MS, using the Water Quality Index (IQA) methodology described by the Environmental Sanitation Technology Company of the state of São Paulo (CETESB), comparing data from the years 2015 to 2017. With the analysis of the obtained results it is concluded that there is improvement in the IQA during the years studied, ranging from regular to good. During this period, it was assumed that there was a growth in the discharge of non-domestic effluents due to the increase in BOD and the decrease in the concentration of thermotolerant coliforms. Mitigating actions and government programs should be applied to improve and preserve environmental quality, as well as continuous monitoring of these water bodies.

Keywords: environmental degradation, water resources, water quality index.

COMPARATIVO ENTRE O COMPORTAMENTO TÉRMICO DE COBERTURA VERDE EXTENSIVA E COBERTURA DE FIBROCIMENTO NO CLIMA DA CIDADE DE SÃO LEOPOLDO, BRASIL

COMPARATIVE BETWEEN THERMAL BEHAVIOR OF GREEN EXTENSIVE ROOF AND FIBROCEMENT ROOF IN THE CLIMATE OF THE CITY OF SÃO LEOPOLDO, BRAZIL

Recibido el 10 de agosto de 2018; Aceptado el 15 de junio 2019

Abstract

Solutions for the thermal performance enhancement and the energy consumption reduction in buildings have been studied in recent years. The use of green roofs, characterized as a multi-layer horizontal sealing system required for a plant complex cultivation, has been presented as a solution with benefits for some types of climate. The study aims to evaluate the thermal performance of this coverage type in São Leopoldo, southern Brazil, compared to a conventional fiber-cement roof. Two experimental prototypes were constructed in this city. The first is representative of a conventional cover in fiber cement 6mm and the second have a green roof. The analysis was performed through measurements of thermal variables with specific sensors. The variation of the external and internal roofs surface temperatures and the variations of the internal air temperatures of both prototypes were evaluated and it was compared with the variations of the air temperature and the global solar radiation of the external environment. After the data collection and analysis of the results, it was verified that the prototype with green roof showed significantly lower daily thermal oscillations in relation to the reference prototype. During the day, warmer period, temperatures were lower relative to the reference prototype and during the night, colder period, were higher. The green roof had a significant capacity to delay and dampen the external thermal amplitude, which contributed to the thermal regulation inside the environment, a favorable feature for the region of study in the period evaluated.

Keywords: sustainable construction, green roof, thermal behavior, energy efficiency.

TRATABILITY PARAMETERS IN CONSTRUCTED WETLANDS APPLIED TO THE REUSE OF DESALINATION RESIDUES

Recibido el 20 de agosto de 2018; Aceptado el 28 de agosto 2019

Abstract

The aim of this research was to evaluate the treatability parameters, which were defined as variables, factors, hydraulic and operating configurations, which, by hypothesis, could potentially influence the process of improving the quality of brine resulting from desalination by reverse osmosis, through the application of Constructed Wetland Systems, cultivated with elephantgrass (*Pennisetum purpureum, Schum*). The studies were conducted on bench scale, within a semi-heated agricultural greenhouse. Twelve experimental units were established, and four treatment configurations were established with three replicates each, operated and monitored for five months, varying according to the operation of the system, whether continuous or static, and also in the hydraulic retention time of three or four days. Water samples were collected at the entrance and exit of each unit, and were analyzed in the laboratory for the physicochemical characterization and, monitoring of parameters: pH, turbidity, salinity, hardness, calcium, chlorides, electrical conductivity and total dissolved solids. The results were submitted to analysis of variance and Tukey's test, at a 95% confidence level, using the statistical program SISVAR. The systems that were submitted to the static regime, with hydraulic retention time of four days, during the first three weeks of operation, showed to be more efficient in the average removal of salinity (53.1%), hardness (69.2%), calcium (66.7%), chloride (44.5%), electrical conductivity (40.7%) and total dissolved solids (86.7%). The plant was able to absorb 0.25% of the sodium ions by its roots for its nutrition, according to the results from the scanning electron microscopy.

Keywords: brine, desalination, effluent treatment, reuse, constructed wetlands.

VOLUMETRIC RELIABILITY OF RAINWATER ACCUMULATION RESERVOIRS DIMENSIONED WITH MONTHLY HISTORICAL SERIES

Recibido el 23 de agosto de 2018; Aceptado el 29 de marzo 2019

Abstract

In order to analyze the difference between the usable volume of water calculated on the basis of monthly and daily precipitation averages, this paper proposes calculating reliability coefficients to the monthly pluviometric series, for different volumes of reservoir. The conclusion that the reliability tends to increase with decreasing of the catchment area and increase of the reservoir volume, occurring however, some exceptions. Important point observed also is that the reliability coefficients can not be used without due consideration of the precipitation conditions of the region, as these can vary considerably in a country. Thus, in future studies about the sizing of the reservoir with monthly historical series, where the reliability thereof is searched, this factor should be taken into account.

Keywords: precipitation, reliability, reservoir.

APLICAÇÃO DA PEGADA ECOLÓGICA NA GESTÃO DE RESÍDUOS SÓLIDOS URBANOS ATRAVÉS DE ANÁLISE DE COMPONENTES PRINCIPAIS: ESTUDO DA CIDADE DE RECIFE, BRASIL

APPLICATION OF THE ECOLOGICAL FOOTPRINT IN THE MANAGEMENT OF SOLID URBAN WASTE THROUGH ANALYSIS OF MAIN COMPONENTS: STUDY OF THE CITY OF RECIFE, BRAZIL

Recibido el 11 de septiembre de 2018; Aceptado el 7 de octubre de 2019

Abstract

The management of municipal solid waste is one of the most complex aspects for municipal managers due to the large volume generated and the cost for the treatment. Thus, tools that provide information for decision making can be useful as indicators of sustainability. The ecological footprint is an indicator of the environmental impact of a product or process and in the case of solid waste, the footprint of the main elements present in the urban flow can be calculated. The objective of this work was to identify the ecological footprint of the recyclable fraction of urban solid waste in the city of Recife, Pernambuco and to evaluate the correlation between waste footprints through analysis of main components, seeking to help in the search of information for management proposals. The waste footprint reveals that the impact of a waste in the environment is directly related to the environmental liabilities of the material, as well as its volume of generation. Through Principal Component Analysis it is possible to visualize graphically correlations between the footprints of the materials and from them to extract information for a more sustainable management proposition.

Keywords: indicators, multivariate statistics, sustainability.

N/P RATIO, CYANOBACTERIA AND TROPHIC STATE INDEX AT THREE RESERVOIRS UNDER A PROLONGED DROUGHT IN BRAZIL'S NORTHEAST

Recibido el 16 de septiembre de 2018; Aceptado el 28 de agosto de 2019

Abstract

The degree of eutrophication was analyzed in three reservoirs at the Brazilian semi-arid tropic, in Ceará State. The study covered a period of one decade and the water sampling was quarterly. The analysis took into account total nitrogen (N), total phosphorus (P), chlorophyll a (Cla) and total cyanobacteria numbers (CB). These quality parameters were complemented with rainfall data (Pp) and percentage of available water volume in the reservoirs (AV%). The percentages of compliance of the Cla concentrations with the environmental standard (CONAMA 357/05) were 60, 6 and 100% in the Banabuiú, Cipoada and Capitão Mor reservoirs, respectively. For total phosphorus, the percentages were 10, 63 and 12%, respectively. For the total count of cyanobacteria, the compliance results were 23, 6 and 86%. The results showed that the degree of eutrophication in Cipoada was higher than in Banabuiú, followed by Captain Mor. The environmental standard does not directly address total nitrogen, but this nutrient correlated positively with P and Cla. Concentrations of total nitrogen may have an equivalent impact to phosphorus. In the study, N: P > 38 ratios predominated in Cipoada and Banabuiú. In Captain Mor the range from 22 to 38 was predominant for the N: P ratio. The TSI values were high, indicating hypertrophy in the Cipoada and Banabuiú, and eutrophic in Captain Mor. Reduction of AV% contributes to the process of eutrophication, with increased nutrients and cyanobacteria counts.

Keywords: semi-arid tropic, eutrophication, climate change.

POTENTIAL OF DIFFUSE POLLUTION FROM STORM WATER RUNOFF IN URBAN HYDROGRAPHIC BASIN

Recibido el 20 de septiembre de 2018; Aceptado el 30 de abril de 2019

Abstract

In the present work the effect of diffuse water pollution due to urban surface runoff to rivers and streams was analyzed. The highlight is the assessment of the polluting effect in a hydrographic basin. In order to do so, the drainage flow was measured and the drained waters of four different urban surfaces (top of basin, residential, commercial and industrial) were sampled in 15 pluviometric events, considering the duration of precipitation. The analyzes of the results were performed comparing the load values of the studied variables, allowing to discuss the contribution of the flow by the first flush phenomena. The runoff waters of the urban portion presented high pollutant loads in all events, mainly for the total solid parameters and chemical oxygen demand. The values showed that the pollution caused by urban surface runoff in areas with commercial, residential and, above all, industrial influences can contribute greatly to the degradation and reducing the quality of receiving water bodies, affecting all the hydrographic basin.

Keywords: first flush, urban runoff, water pollution.

PROLONGED DROUGHT AND IONIC CONTENT OF THE WATER OF TWO BRAZILIAN SEMIARID RESERVOIRS

Recibido el 26 de septiembre de 2018; Aceptado el 7 de octubre de 2019

Abstract

The main objective of this work is to investigate the hydrochemical behavior and the ionic content in two reservoirs in Ceará, Northeast Brazil, due to changes due to prolonged drought in the region. The study comprised the surface waters of the Banabuiú and Pedras Brancas reservoirs, with samples collected between 2005 and 2017. The parameters monitored were electrical conductivity, total hardness, higher ions, hydrogen potential, total dissolved solids and temperature. In addition, a hydrochemical approach was performed from the Piper, Gibbs and Chadha diagrams. The predominant cations were those of greater mobility for both dams, while bicarbonate anion was more incident in Banabuiú and chloride in Pedras Brancas. The surface waters of the Banabuiú reservoir were classified as bicarbonated mixed, while Pedras Brancas was predominantly chlorinated sodium. The Gibbs diagram was important to show the dominance of the action of the hydrological cycle on the interaction of the cations with the rocks and the interchange of the anions with the rocks prevailing the effect of the rains and the evaporation. For White Rocks, evaporation had a predominant effect in both cases, and the interaction between rocks and surface water occurred predominantly between cations. The Chadha diagram indicated that the waters of Banabuiú had greater interchange between the mobile cations and favored by surface runoff for bicarbonate. For White Stones, the reversals of the left inferior quadrant, referring to the dominance between Na^+ and Cl^- and indicating salinization, were emphasized.

Keywords: surface waters, water scarcity, ionic interaction.

EVALUATION OF METEOROLOGICAL AND HYDROLOGICAL DRY INDICES IN RELATION TO THE IMPACT OF WATER ACCUMULATION IN RESERVOIR: A CASE STUDY FOR THE RESERVOIR OF JUCAZINHO-PE

Recibido el 1 de octubre de 2018; Aceptado el 28 de octubre 2019

Abstract

This work aims to analyze the dry state in a water accumulation reservoir and assess the severity classification difference in different time horizons over the years in order to determine what the best drought indices that can be used as triggers for drought mitigation actions. For this, we used the SPI index (Standardized Precipitation Index), SPEI (Standardized Precipitation-Evapotranspiration Index), SRI (Standardized Runoff Index), IE (State Index), IS (Synthetic Index) and NM (Target levels), where such indices were compared by a qualitative and quantitative analysis. The results showed that the drought afflicting Jucazinho reservoir or dry severity level of the same, it is not always occur due to natural conditions which the reservoir is exposed. Another important finding is that content such as SPI, SPEI and SRI cannot keep the fluctuation of the water stock in the same speed as do occur.

Keywords: drought state, drought indexes, reservoir.

Abstract

The growing demand of actions for soil remediation has resulted in the development of alternative technologies, especially for applications of techniques *in situ*, caused for the many forms of contamination of soil and underground water with petroleum hydrocarbons. The present work proposed an electro-bioremediation technique to evaluate the capacity degradation of the pollutants through microorganisms present in the polluted soil. The monitoring of the degradation of hydrocarbons was accompanied through chemical analyses of Total Petroleum Hydrocarbons (TPH), Benzene, Toluene, Ethylbenzene, and Xylene (BTEX), Polycyclic Aromatic Hydrocarbons (PAH). The microbiological activity was monitored through analyses of Colony-Forming Unit (CFU). The results showed that rates of degradation of the xylene, toluene and ethylbenzene had an order of 69%, 60% and 10%. The microbiologic activity presented an increase of 12.5 times for the Mould and Yeasts, and of 178.5 times for aerobic microorganisms. The isolation and biodegradation analysis pointed the existence of 26 different morphotypes, of these, 20 morphotypes (77%) possess capacity to degrade hydrocarbons that, 60% were found in the areas of influence of the cathode and 40% of the anode. The yeast-like material was isolated and identified, where the predominant genus was Penicillium (50%), Paecilomyces 16.6%, Trichoderma 16.6 % and Cladosporium 16.6%.

A SUSTENTABILIDADE NO COMPORTAMENTO DOS FREQUENTADORES DE UM CAMPUS UNIVERSITÁRIO: ANÁLISE POR MEIO DE PAINEL INTERATIVO

SUSTAINABLE BEHAVIOUR OF USERS OF A UNIVERSITY CAMPUS: ANALYSIS THROUGH AN INTERACTIVE PANEL

Recibido el 17 de octubre de 2018; Aceptado el 30 de abril de 2020

Abstract

The term sustainable development, as conceived in the Brundtland report in 1987, is by definition to allow the present generation to meet their needs without compromising the future generations. However, cities have been suffering intensely with problems such as the increased accumulation of waste, difficulties of urban mobility, the precariousness of public spaces and the low availability of green areas. Therefore, this paper aims to study the perception of students, professors and employees on sustainability issues, emphasizing the importance and impact of individual behavior on problems faced by cities. To do so, an Interactive Panel composed of 6 questions was designed to find out the level of engagement of the academic community and other users of the University of Passo Fundo main campus concerning sustainability. More than a hundred responses were received and the results were analysed using descriptive statistics. These results obtained demonstrate that most respondents describe positive behaviors in relation to the issues addressed, and suggest issues that deserve improvement in order to contribute to local sustainability.

Keywords: sustainable campus, environmental education, multivariate statistics.

Abstract

Benzene, toluene e xylene are present in gasoline and so a strong threat to the environmental and to public health due to the storage tanks leaks and varied industrial activities. This work aimed at the removal of 30 mg/L of benzene and toluene and 15 mg/L of xylene in aqueous medium by fungal batch reactors. It was also added 100 mg/L of ethanol. The choice of the kind and concentration of cells in the inoculum reactor sequencing batch was made from assay with separated variation of spores concentration of *Aspergillus niger* AN400 e *Penicillium* sp. (2×10^4 , 2×10^6 e 2×10^9 esporos/mL). The sequencing batch reactor (5 L) was inoculated with *Aspergillus niger* and operating at 48 h cycles. The immobilized biomass grown filamentous form. Registered organic matter removal (81%), benzene (60%), toluene (96%) and xylene (50%), respectively. After 4 months of reactor operation, *Penicillium* sp. was found as a contaminating species in the biofilm.

RAINFALL INTENSITY EQUATION APPLICATION OF GURUPI – TOCANTINS

Recibido el 18 de octubre de 2018; Aceptado el 30 de abril 2020

Abstract

The obtaining of the rainfall intensity equation is of fundamental importance for the taking of measures that aim at minimizing problems of hydrological origin, mainly in the control of floods. Among these measures are the sewers that are widely used in the engineering field for the realization of the surface runoff of a sub-basin. This equation is formed by the relationship between the intensity, duration and frequency that provides the parameters K, a, b and c beyond the return and concentration times. This article seeks to determine the parameters of the Gurupi-TO rainfall intensity equation, as well as to compare it with the equation provided by the Pluvio 2.1 software in the application of a rectangular culvert draining water in the Córrego Mutuca sub-basin. The parameters of the rainfall intensity equation $K = 1348.212$; $a = 0.064$; $b = 15.587$; $c = 0.770$. The sections of the culvert presented lower values with the equation presented in this study in relation to the equation provided by the software Pluvio 2.1. With the dimensions that the manhole presents currently occurred flood of the estradal body after 2 minutes of the beginning of the Rain.

Keywords: IDF curve, maximum flow, Pluvio 2.1, manhole.

EQUACIONAMENTO DOS VIESES EM CHEIAS DE PROJETO REFERÊNCIA E SIMULADA A PARTIR DE HIETOGRAMAS SINTÉTICOS: CASO DE ESTUDO BACIA HIDROGRÁFICA DE SÍTIOS NOVOS – CEARÁ

EQUATING THE BIAS FROM REFERENCE DESIGN FLOOD AND SIMULATED DESIGN FLOOD OBTAINED FROM SYNTHETIC HYETOGRAPH: CASE STUDY OF SÍTIOS NOVOS BASIN

Recibido el 25 de octubre de 2018; Aceptado el 30 de abril de 2020

Abstract

Water resource planning should be more coherent and concise so that the tool used in its management could be efficient following waterbody company instructions and guidelines. The temporal distribution of irregular precipitation in the Brazilian northeast (specifically in Ceará), requires a special attention for adoption of several equipment for water security, water supply, water management and other appropriate purposes. The objective of this paper is to improve the technique (correction factor) of bias removal in the design floods (reference and simulated) in different return periods for the Sítios Novos reservoir. After the simulation of the design storm (synthetic hyetographs) in different return period and flood generation, an underestimation of the respective flow rates was observed in detriment of the referential design floods and based on the mathematical calculation of bias correction factors in 6 different forms of rainfall distribution. These factors obey a temporal and spatial invariability and have presented an overestimation of the simulated flood in the course of their use. In this sense, we opted for the method of trial and error with the objective of finding an equality of the design flood (simulated and reference) in the same return period of study in a given watershed such as the Sítios Novos Basin – Ceará.

Keywords: design flood, synthetic hyetograph, return period, correction factor.

ESTUDO DAS CONCENTRAÇÕES DE CHUMBO DETECTADAS NO SOLO DE OLARIAS NO DISTRITO DE MARAGOGIPINHO, MUNICÍPIO DE ARATUÍPE, BAHIA, BRASIL

A STUDY OF THE LEAD CONTENTS DETECTED IN SOILS FROM ARTESIAN POTTERY ACTIVITIES IN MARAGOGIPINHO TOWN, BAHIA, BRAZIL

Recibido el 26 de octubre de 2018; Aceptado el 30 de abril de 2020

Abstract

This study evaluated the concentrations of lead (Pb) detected in surface soil of artisanal potteries located in the district of Maragogipinho, Aratuípe Town, Bahia, Brazil. Field samples were collected and a portable x-ray fluorescence analyzer (XRF) were used to determined Pb concentrations. The result showed that 62% of artisanal potteries were above the lead limits established by CONAMA N° 420/2009 for residential areas (300 mg/kg). The use of the metal in the vitrification ceramic process, the release of this element in the firing step and the inadequate disposal of broken pieces in a landfill were identified as the main sources of soil contamination by Pb. The concentration values detected near the potteries indicated that the a larger portion of soil was contaminated by Pb from the artisanal ceramic activities carried out in that location.

EVALUATION OF THE USE OF INFILTRATION TRENCHES FOR REDUCTION OF RUNOFF IN CRATO-CE CITY, BRAZIL

Recibido el 1 de noviembre de 2018; Aceptado el 18 de diciembre de 2019

Abstract

The urbanization process of the last decades worldwide has caused several impacts on the environment, especially in the hydrological cycle, bringing with it an increase in the amount and magnitude of urban floods. The main objective of the present study was to evaluate the impact that the urbanization process of an urban area of the city of Crato-CE has on the surface drainage and to present a proposal for flood reduction through the simulation of infiltration trenches implanted in the public sidewalk receiving waters exclusively from the roofs of buildings. For the simulations, the computer model Storm Water Management Model - SWMM and the computer program UFC8 were used. The results showed that the modeled neighborhood after the total occupation of the buildings and paving of the streets should present problems in the surface runoff of rainwater and that the use of infiltration trenches can considerably reduce the flow peaks. The use of infiltration trenches may have benefits that go far beyond reducing flood problems in the region under study, and may reduce them in other downstream areas and favor the increase of local underground water resources reserves.

ELECTROCOAGULATION APPLIED TO LANDFILL LEACHATE TREATMENT

Recibido el 3 de noviembre de 2018; Aceptado el 30 de abril de 2020

Abstract

Landfill leachate is characterized by high polluting potential. In this context, the aim of this research was to evaluate the landfill leachate treatment performance by electrocoagulation varying the current densities (DC) and electrolysis time in color, turbidity, COD, BOD and Abs₂₅₄ removal, the effluent pH was monitored during the process. An electro reactor was used containing 8 monopolar iron electrodes, spaced 1 cm apart. The electrocoagulation tests were performed in triplicate, with the application of electric currents of 2, 3, 4 and 5 A, generating DCs: 64.4, 96.64, 128.86, 161.08 A/m², for each DC applied 15, 30, 60 and 90 minutes of electrolysis times were tested. It was observed the pH elevation when higher electrolysis times and DC's applied. For all parameters evaluated the highest removal efficiencies occurred with the application of DC 161.08 A / m², in 30 minutes of electrolysis there was 84% of color removal and in 60 minutes 87% of BOD removal and 44% of Abs₂₅₄, however for the parameters Turbidity and COD the highest removal efficiencies (82% and 46%) occurred in 90 minutes of electrolysis.

Keywords: electrolytic treatment, leachate, color, turbidity, organic matter removal.

ENERGY PERFORMANCE AND WASTEWATER TREATMENT IN AN ARTIFICIALLY ILLUMINATED CONTINUOUS PHOTOBIOREACTOR

Recibido el 4 de noviembre de 2018; Aceptado el 5 de febrero de 2020

Abstract

The use of Light Emitting Diodes (LEDs) as a light source have important advantages: high efficiency, high durability and low energy consumption. LEDs can be applied to the illumination of photobioreactors used in the treatment of wastewater for the removal of organic matter, nutrients and pathogens. Most of the research found in the literature makes use of laboratory-scale photobioreactors (usually 1L) and operated in batch mode. Despite the low energy consumption of the LEDs, its use for continuous photobioreactors is questioned, since the energy performance for these systems has not yet been evaluated. Microalgae are cultivated in photobioreactors and, besides promoting the treatment of wastewater, their biomass can be reused to generate different bioproducts. This research evaluated the efficiency of an open photobioreactor illuminated by LED, simulating the operation of a High Rate Algal Pond (HRAP), in the treatment of synthetic wastewater and in the energy aspect as a function of artificial light. The light intensity was $815 \mu\text{E}.\text{m}^2.\text{s}^{-1}$. The system was operated continuously under a 7-day hydraulic retention time (HRT). Microalgae productivity was $6.80 \pm 1.9 \text{ g}.\text{d}^{-1}.\text{m}^{-2}$, and the net oxygen production was $0.83 \text{ g}.\text{L}^{-1}$. The system presented stability and efficiency in the removal of organic matter, represented by Chemical Oxygen Demand (COD), being $90.3 \pm 1.7\%$ of removal. However, high values of energy consumption indicators were obtained, being $368.8 \text{ kWh/kg COD removed}$, 287 kWh.m^{-3} and $51.66 \text{ kWh (hab.d)}^{-1}$.

Keywords: environmental technologies, high rate algal pond, microalgae.

MODELAGEM HIDRODINÂMICA E AVALIAÇÃO DO DECAIMENTO DO FÓSFORO EM UM LAGO URBANO HIPEREUTRÓFICO

HYDRODYNAMIC MODELING AND PHOSPHORUS DECAY EVALUATION OF A HYPEREUTROPHIC URBAN LAKE

Recibido el 8 de noviembre de 2018; Aceptado el 28 de junio de 2019

Abstract

This study aimed to analyze the hydrodynamics of a hypereutrophic urban lake located in Fortaleza-CE, Brazil, applying the 2D modeling software CE-QUAL-W2, as there is a lack of these studies on the Northeast region of Brazil. Field data along with literature available information were used to insert lake information on the model, so the scenarios for rainy and drought periods were performed for velocity, temperature and residence time (RT). Time series for RT and phosphorus decay rate (K) were performed and compared to the results found using the complete mixing approach. The modeling outcomes showed RT values on the range from 8 to 80 days, with higher values obtained for the dry season, as expected. It was also observed a slight thermal stratification for the dry season, which reduces for the rainy season. This scenario was corroborated by the results regarding the RT. Finally, when the RT and K values obtained with the 2D model were compared to the ones obtained with the complete mixing approach, it was found that this is a good approximation for this reservoir.

Keywords: CE-QUAL-W2, hydrodynamic modeling, urban lake, phosphorus.

SITUATIONAL ANALYSIS OF THE SANITARY CONDITIONS OF THE REGISTERED QUILOMBOLA FAMILIES IN CADÚNICO, 2016

Recibido el 8 de noviembre de 2018; Aceptado el 28 de junio de 2019

Abstract

The present study aimed to develop a situational analysis of the sanitary conditions of the houses of the quilombola families registered in the Cadastro Único for Social Programs of the Federal Government (CadÚnico). For this purpose, the CadÚnico family database for the year 2016 was employed, available by the former Ministry of Social Development, now the Ministry of Citizenship. Descriptive statistical analyzes of five variables related to basic sanitation and one socioeconomic variable were carried out. The results show that the main form of water supply for the quilombola families is through wells or springs (45.29%), there is still a large portion of households that don't have channeled water (44.99%), bathroom or toilet (28.64%), and adequate destination of domestic sewage (7.85% have open sewage and 60.18% use rudimentary latrine), the household waste collection service doesn't exist in 70.58% of the households, and most of the residents burn or bury the waste in the soil. It was observed that a large portion of families lived in extreme poverty (71.82%). Comparing the results by locality (urban or rural) it is observed that there is a clear asymmetry access to basic sanitation services, being the best condition in urban locations. Families living in the North and Northeast regions are those who live with the worst sanitation conditions and should be prioritized as the focus of interventions. Thus, the present study indicates that even with the aid of government programs and public policies, a large part of quilombola families still live with inadequate sanitary conditions.

Keywords: public policy, quilombolas, sanitation.

INTERFACE GRÁFICA SOB A UTILIZAÇÃO DA LÓGICA FUZZY: A QUALIDADE DE ÁGUA EM RESERVATÓRIOS

GRAPHIC INTERFACE UNDER THE USE OF FUZZY LOGIC: WATER QUALITY IN RESERVOIRS

Recibido el 10 de noviembre de 2018; Aceptado el 10 de octubre de 2019

Abstract

The scarcity of rainfall in several Brazilian regions, associated with long periods of drought and high evaporation rates, currently challenges water management models. The mathematical models of water quality are an alternative to improve the control of the management of these resources. Aiming at establishing a computational program that provides model responses, the research aims to develop a graphical interface capable of allowing data entry in the system in a simple and intuitive way, together with graphical tools to quickly analyze the processed data. Methodologically, Fuzzy logic was used for data processing and interface construction, in order to study the water quality in reservoirs. As a result, a quick and objective interface was obtained, combined with the analysis of results by means of graphs. It is concluded that the presented interface has feasibility of implementation, since it gives greater agility, practicality and greater amplitude in the analysis of the obtained results.

Keywords: interface, mathematical model, water quality.

COMPARATIVE ANALYSIS OF DISINFECTION TECHNIQUES IN WASTEWATER OF ETE USING MICRORGANISM INDICATORS

Recibido el 21 de noviembre de 2018; Aceptado el 30 de abril de 2020

Abstract

This study evaluated the efficiency of individual disinfection methods using peracetic acid (PAA), hydrogen peroxide (H_2O_2) and UV radiation and the combined disinfection methods of PAA/UV and H_2O_2 /UV for final effluent of wastewater treatment plant. It was evaluated the performance of the disinfectants used according to the inactivation efficiency of the indicator microorganisms, *Escherichia coli*, total coliforms, *Clostridium perfringens* and coliphages. To the experimental conditions adopted, the concentrations of PAA and H_2O_2 were 2 and 3 mg L⁻¹ and contact time of 10 and 20 minutes, with mean exposure doses ranging from 30.62 to 206.65 mWs.cm² for UV radiation. The PAA/UV and H_2O_2 /UV disinfection consisted of a combination of the times, concentrations and doses of disinfectants adopted in individual methods. The results obtained in the disinfection tests with peracetic acid and hydrogen peroxide did not promoted significant inactivations for any of the indicator microorganisms, under the experimental conditions employed. The UV radiation showed to be more effective in the reduction of all the indicator microorganisms, showing superior results compared to the other disinfectants. The disinfection processes PAA/UV and H_2O_2 /UV showed similar inactivations to those obtained by UV radiation method. *Clostridium perfringens* was the microorganism that showed higher resistance to inactivation for all disinfectants used. The occurrence of synergism was observed for *Escherichia coli*, *Clostridium perfringens* and coliphages, only in the concentrations and times of superior contacts. There was a significant increase of 1 log of inactivation for *C. perfringens*, when combined H_2O_2 /UV disinfection method was used.

Keywords: advanced oxidative processes, hydrogen peroxide, peracetic acid, UV radiation, synergism.

Alessandra Maysa Araújo Rodrigues ²

OZONIZATION AND GAS STRIPPING IN POST-TREATMENT OF SANITARY EFFLUENT

Recibido el 2 de diciembre de 2018; Aceptado el 30 de abril de 2020

Abstract

The paper of the experimental objective focused on the post-treatment of sanitary effluent through ozonation and gas stripping by the bubbling of pure nitrogen, aiming at the removal of organic compounds. The sanitary effluent matrix comes from a sewage treatment plant that uses the UASB (Upflow Anaerobic Sludge Blanket) reactor as a secondary treatment followed by flocculation/floatation in a Flot-Flux type channel. As for the experimental configuration, in the ozonation were applied loads of 2.07, 5.38 and 7.15 gO₃/h (surface application rates of 127.4, 382.2 and 636.9 L/min.m², respectively) in a bubbling column to the contact times between the ascending bubbles and the liquid medium of 30 and 60 minutes. The same experimental configurations were adopted in the experiments of gas stripping from the injection of the inert gas N₂. In the ozonation and gas stripping, respectively, there was an increase in pH values (10.4% ± 2.2 and 20.2% ± 1.0) and reductions in color (89.1% ± 4.1 and 42.4% ± 6.9), turbidity (68.3% ± 9.8 and 36.5% ± 18.6), COD (70.1% ± 8.9 and 35.5% ± 7.4) and ammoniacal nitrogen (10.8% ± 1.5 and 9.3% ± 0.5) parameters; however, nitrate was only raised in the ozonation tests (on the order of 6 times), remaining constant in the gas stripping. Statistical analysis Anova states that the analyzed parameters were not influenced by injected gas dosages, but only by contact times. Ozonation was able to promote the removal of organic compounds in the post-treatment of sanitary effluent, while the gas stripping technique was able to remove volatile organic compounds and free ammonia.

Keywords: gas stripping, sanitary effluent, ozonation, post-treatment.

USE OF PESTICIDES AND ACUTE POISONING IN RURAL POPULATION OF SAN BALTAZAR CHICHICAPAM, OAXACA, MEXICO

Recibido el 19 de diciembre de 2018; Aceptado el 30 de abril de 2020

Abstract

In Oaxaca, agriculture is the main activity in the primary sector and in rural communities. Unfortunately, agricultural production is exposed to the indiscriminate use of agricultural inputs, in particular, to pesticides. These inputs represent a potential risk to public health and the environment. The objective of this research was to document the management, use behaviors and acute poisoning caused by pesticides used in agriculture in the community of San Baltazar Chichicápam, Oaxaca, Mexico. Through surveys to 50 producers, information was obtained on the types of crops and pesticides used, the behaviors of use, as well as the signs and symptoms of acute pesticide poisoning (APP). The most important crops were corn and beans (78%), alfalfa (68%), chickpea (28%), tomato (20%) and flowers (20%). We identified 37 active ingredients (IA) of pesticides, 17 are used in corn, 15 in beans, 15 in alfalfa, 23 in tomato and 12 in flowers. The organophosphorus insecticide methamidophos of Toxicological Category II (TC II), is applied mainly in corn, beans and alfalfa. In the rest of the crops, insecticides, herbicides and fungicides of different TCs are used. Most farmers do not use safety measures when using pesticides. 66% of the population have at least one APP symptom. The main pesticide associated with these symptoms was methamidophos. The health of the population under study is at risk due to exposure to the diversity of pesticides identified.

Keywords: acute pesticide poisoning, Chichicapam, Oaxaca, pesticides.

ISOLAMENTO E CARACTERIZAÇÃO MORFOLÓGICA DE MICRORGANISMOS PRESENTES NO PROCESSO DE COMPOSTAGEM DE RESÍDUOS DE ORIGEM VEGETAL

ISOLATION AND MORPHOLOGICAL CHARACTERIZATION OF MICROORGANISMS PRESENT IN THE PROCESS OF COMPOSTING LEAF WASTES

Recibido el 20 de diciembre de 2018; Aceptado el 7 de septiembre de 2019

Abstract

The management of urban solid waste (USW) represents a major environmental problem nowadays. Composting is one of the proposed solutions to make possible the reuse of part of the organic waste, constituting a controlled aerobic process, developed by a diverse population of microorganisms. The temperature is an important factor that interferes in the continuity of the microbial populations and its it may indicate the phases of degradation. The identification of the microorganisms present in composting is an important step to identify those more efficient, allowing a better control of the process and consequent better efficiency. Therefore, the present study aims to isolate and characterize, from morphological and phenotypic criteria, the microorganisms present in the final product of a leaf compost. The microorganisms were isolated from the final product of this composting process (pilot scale), carried out in a public institution in Belo Horizonte, Brazil. Selective and nonselective culture medium were used to obtain a greater possible variety of microorganisms. For the morphological evaluation of the plants a Gram staining technique was used. Of the analyzed samples, 44% are Gram positive bacilli, 22% Gram negative rods, 6% Gram positive cocci, 28% Gram negative cocci. The predominant aerobic bacteria found were those belonging to the genus *bacillus* spp., Indicating the relevance of these microorganisms for the accomplishment of the composting process. New studies are needed to effect the identification of the species present in the processes of leaf wastes composting and the characterization of the biotechnological potential of these bacteria.

Keywords: organic compost, decomposition, efficient microorganisms.

ANÁLISE DE SISTEMAS DE TRATAMENTO DE EFLUENTES DE ABATEDOUROS BOVINOS POR LAGOAS DE ESTABILIZAÇÃO E POR REATOR UASB SEGUIDO DE LAGOA DE POLIMENTO

ANALYSIS OF SYSTEMS OF TREATMENT OF EFFLUENTS OF BOVINE LAYERS BY ESTABLISHMENT LAKES AND BY UASB FOLLOWED REPLACER OF POLISH POND

Recibido el 21 de diciembre de 2018; Aceptado el 30 de abril de 2020

Abstract

Brazil is among the largest beef producers in the world and this industrial sector has a fundamental role in the country's economy. It's notorious that the activities carried out in the slaughterhouses have a high polluting potential of the water bodies, where the generated effluents are released. The treatment of these effluents can be carried out by combining chemical, physical and biological methods. After treatment, the effluent characteristics must comply with the parameters established by current legislation. The objective of this work is to evaluate and analyze the efficiency of two treatment systems of the effluent generated by a slaughterhouse in the state of Tocantins, the first being the traditional system of stabilization ponds and the second consisting of a UASB reactor and a polishing pond. The estimated BOD removal efficiency for the proposed systems was over 90%, above the 60% efficiency required by CONAMA Resolution No. 430 and, therefore, applicable to the treatment of slaughterhouse effluents.

Keywords: anaerobic treatment, organic matter, industrial waste, UASB reactor, stabilisation ponds.

ORGANIC COMPOUND OBTAINED BY THE PROCESS OF COMPOSTING OF SEWAGE SLUDGE WITH INOCULATION OF BIORREMEDIATOR

Recibido el 1 de octubre de 2019; Aceptado el 31 de enero 2020

Abstract

In order to facilitate and accelerate the process of waste Bio-oxidation to obtain products with better quality, stabilized and sanitized, several effective microorganism-based bioremediators are available. The efficiency of the bioremediator may vary according to the type of waste and bioxidation process used. However, its use and effectiveness can be considered contradictory, not presenting standardization of responses to similar situations. The purpose of this study was to analyze and compare the organic compound formed by composting process in the presence and absence of the biorremediador inoculation in sewage sludge from an anaerobic treatment. The results showed that the bioremediator in the composting process is more useful in occasions when the microorganisms used are compatible with the characteristics of the residue, so in this study there was no evidence of acceleration of the composting process.

Keywords: biorremediador, composting, inoculant, organic compound, sewage sludge.
